PROJECT REPORT

On

"ELECTROMAGNETIC CRANE."

Submitted in partial fulfilment of the requirements of 12th grade physics course of Central Board of Secondary Education (cbse), Delhi, India

By

FARSANA NOUSHAD SINI

UNDER THE GUIDANCE OF

Mrs. Udaya Unnikrishnan

SHANTINIKETAN INDIAN SCHOOL DOHA QATAR

AFFILIATED TO THE CENTRAL BOARD OF SECONDARY EDUCATION, DELHI APPROVED BY THE MINISTRY OF EDUCATION, STATE OF QATAR.

2026 - 2027

BONAFIDE CERTIFICATE

ACKNOWLEDGEMENT

I would like to express my sincere gratitude to **Mr. Rafeeq Rahim**, Principal of Shantiniketan Indian school, Doha, Qatar, for providing me with this opportunity and all the necessary facilities during the course of study.

I am sincerely thankful to **Mrs. Udaya Unnikrishnan,** Physics teacher of XII A, for inspiring me to work on this fascinating project. Her invaluable guidance, constant encouragement, and persistent support throughout the course of this project have been instrumental in its successful completion.

I further express my acknowledgement to my parents and friends, who were directly or indirectly involved in the completion of this project

Student Name: Farsana Noushad Sini.

Place: Doha, Qatar. **Class and Division:** 12 A **P. No:** P8661**. Date:**

AIM

• To study the various effects of the curvature of space-time and to explore its significance in modern physics and cosmology.

INTRODUCTION

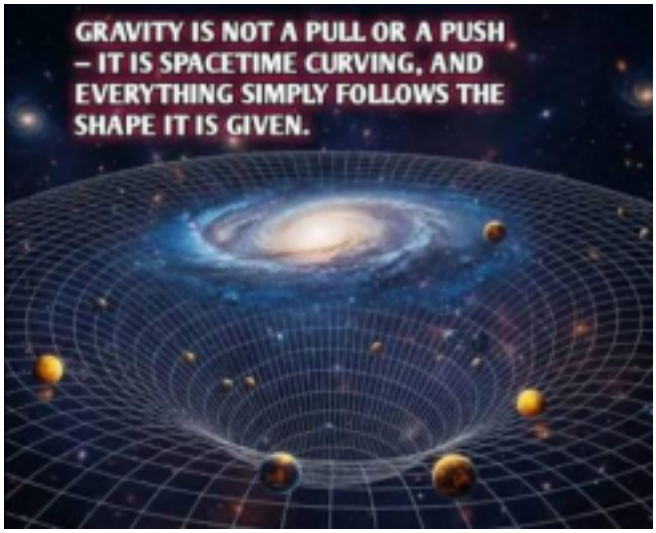

The universe is filled with fascinating phenomena that scientists have tried to understand for centuries. One of the greatest mysteries is gravity, the force that keeps planets in orbit, causes objects to fall to the ground,

and holds galaxies together. For centuries, gravity was explained by Sir Isaac Newton as a force of attraction between two masses. However, in 1915, Albert Einstein introduced the **General Theory of Relativity**, which transformed our understanding of gravity. According to this theory, gravity is not simply a force but the result of the curvature of space-time caused by the presence of mass and energy.

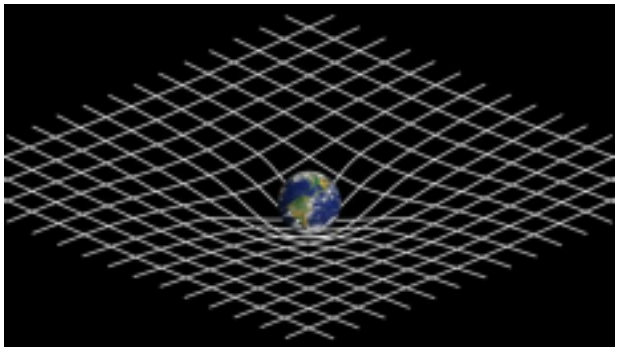

Space-time is a four-dimensional framework that combines the three dimensions of space with the dimension of time. When a massive object such as the Sun, a planet, or a black hole exists in space, it bends the surrounding space-time. As a result, other objects move along these curved paths, giving the appearance that they are being pulled by gravity.

The curvature of space-time helps explain many fascinating phenomena in the universe, including the motion of planets around the Sun, the

bending of light near massive objects (gravitational lensing), the formation of black holes, the existence of gravitational waves, and the slowing of time in strong gravitational fields (gravitational time dilation). These predictions have been confirmed through scientific observations and experiments, making Einstein's theory one of the most successful theories in modern physics.

WORKING PRINCIPLE

The concept of the curvature of space-time is one of the most remarkable achievements in modern physics. The scientific principle behind this project is based on Albert Einstein's General Theory of Relativity

proposed in 1915, it changed the way scientists understand gravity. Rather than viewing gravity as a force acting between objects, Einstein explained it as the bending of space-time caused by mass and energy.

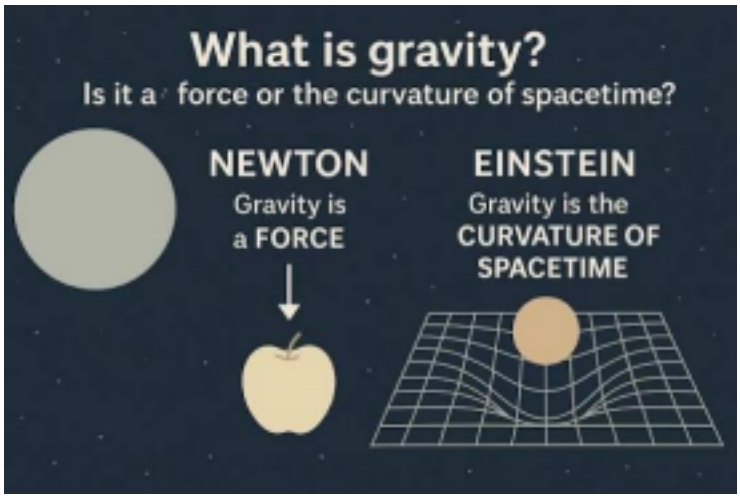

In other words, mass and energy distort the fabric of space-time, creating what we call as gravity. The amount of curvature depends on the mass of the object the greater the mass, the greater the curvature.

Gravity feels strongest where space-time is most curved, and it vanishes where space-time is flat. This is the core of Einstein's theory of general relativity.

The study of space-time curvature is not only important in astronomy and astrophysics but also has practical applications in everyday life. For

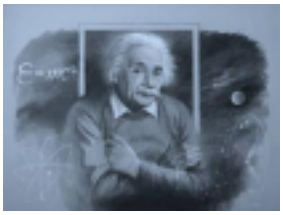

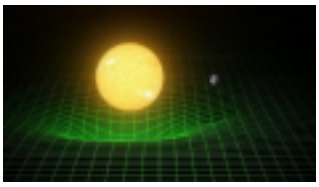

example, satellite-based navigation systems such as GPS must account for the effects of relativity to provide accurate location information.

This project aims to explore the concept of the curvature of space-time, understand its various effects, and highlight its importance in explaining the behavior of the universe and its contribution to modern science and technology.

TIME LINE

	1687	<u>Isaac Newton</u> Publishes *principia Mathematica* Introduces the law of universal gravity, which explains gravity as a force acting between masses.

	1905	<u>Albert Einstein</u> Publishes the special theory of relativity, introducing relation between space and time.
	1915	<u>General theory of relativity</u> Einstein proposes that gravity is caused by space-time curvature due to mass and energy
	1916	<u>Prediction of Gravitational Waves</u>
	2019	<u>First Image of a black hole</u>
	Present Day	The study of space – time curvature continues to advance our understanding of black holes, neutron stars, gravitational waves, cosmology, and technologies such as GPS.

Demonstration of the Curvature of Space-time Using a Stretchable Fabric Model.

GOAL: To demonstrate how a massive object curves space-time and influences the motion of nearby objects using a simple

physical model.

MATERIALS REQUIRED

- Round plastic tub or bowl (without lid).
- Stretchable fabric.
- 6 – 10 cloth clips.
- One heavy ball (cricket ball or steel ball).
- 3–5 small marbles.

PROCEDURE

- Stretch the fabric tightly over the plastic tub and secure it with cloth clips.
- Place the heavy ball (Sun)at the center of the fabric.

• Roll a marble gently across the fabric from different directions. • Observe the marble's path around the heavy ball.

• Repeat the activity with different rolling speeds.

OBSERVATION

• The heavy ball created a depression in the fabric.

• The marbles followed curved paths around the depression. • Faster marbles travelled farther before curving.

• The model demonstrated how a massive object influences the

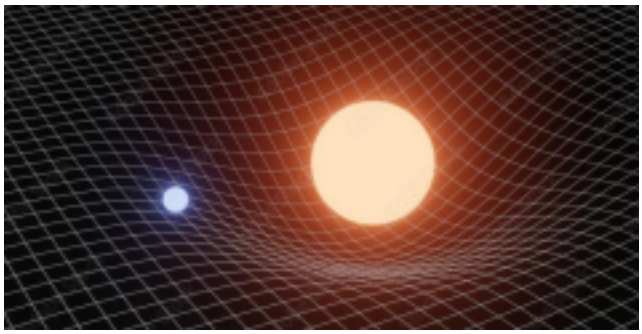

motion of nearby objects.

RESULT

The model showed that a massive object creates a curvature, causing nearby objects to move along curved paths. This provides a visual analogy for Einstein's concept of curved space-time.

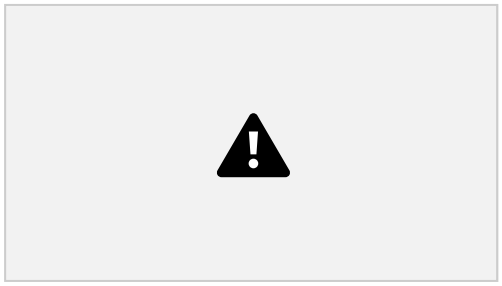

APPLICATIONS

1.Global Positioning System (GPS):

GPS satellites experience weaker gravity than Earth, so their clocks run slightly faster due to space-time curvature. Scientists correct these time differences to ensure accurate navigation.

Application: Navigation in cars, airplanes, ships, smartphones, and emergency services.

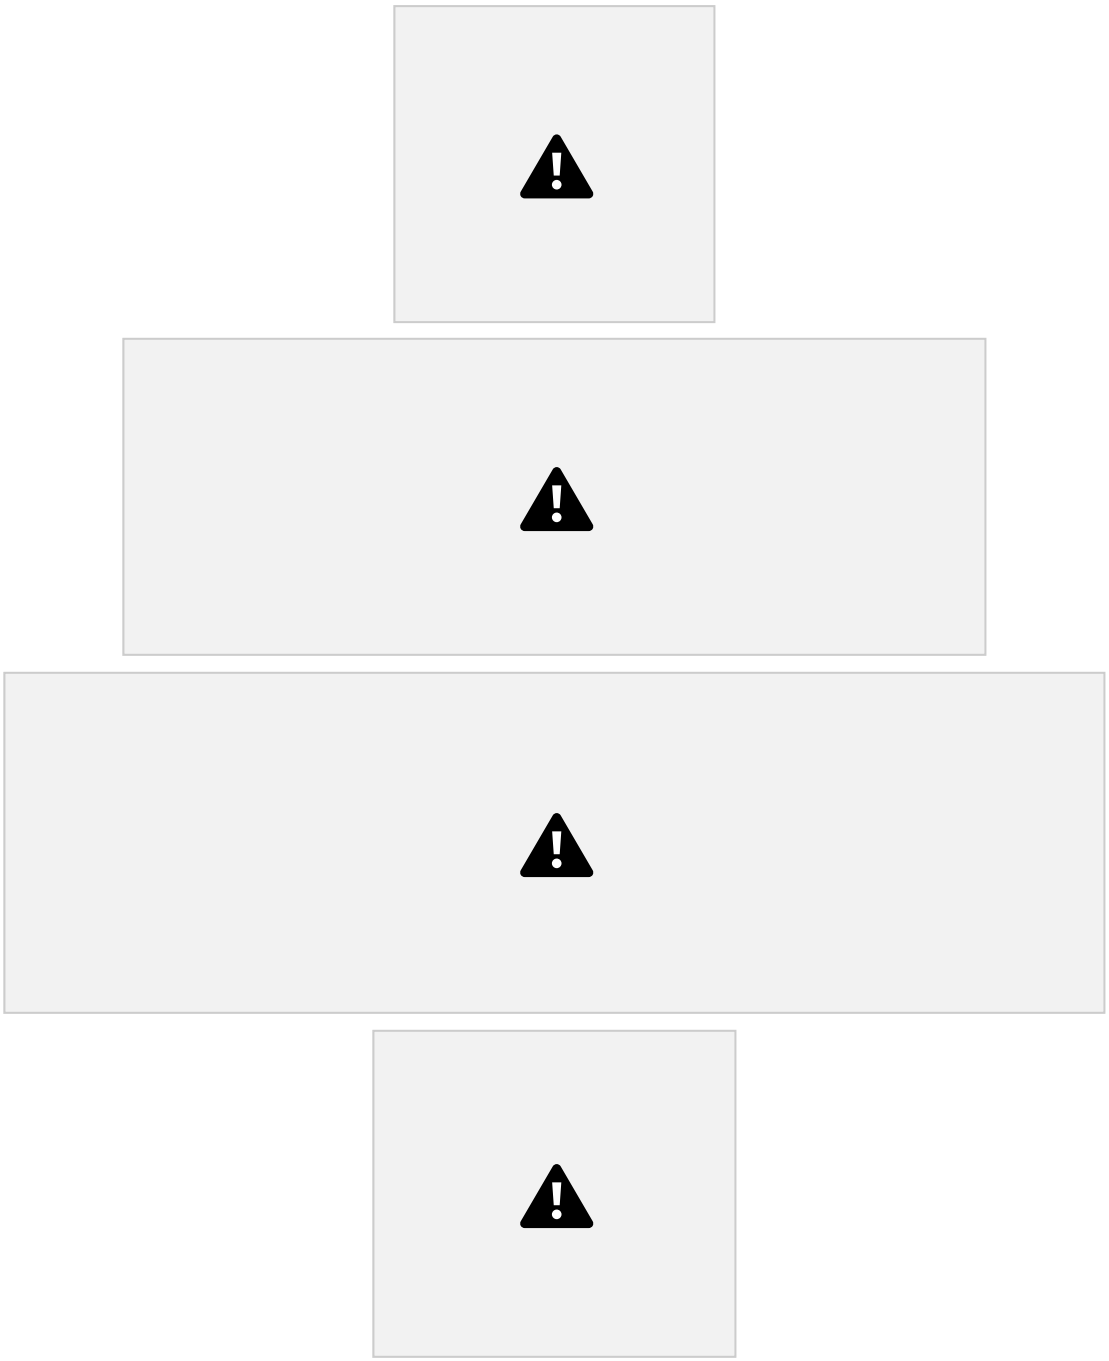

2. Black Hole Imaging

Space-time curvature around black holes bends light, allowing scientists to capture and study black hole images.

3. Gravitational Lensing:

Massive objects such as galaxies bend the path of light passing near them, allowing astronomers to observe distant galaxies, detect dark matter, and discover exoplanets.

4. Spacecraft Navigation - Relativity helps calculate accurate paths for satellites and deep-space missions.

5. Gravitational Waves

Collisions of massive objects create ripples in space-time, helping scientists study black holes and other cosmic events.

6.Cosmology

Space-time curvature helps explain the expansion, structure, and evolution of the universe.

PRECAUTIONS

• Stretch the fabric tightly to avoid wrinkles.

• Keep the model on a flat, stable surface.

• Roll the smaller ball gently without applying extra force. • Ensure the fabric remains evenly stretched throughout the demonstration.

• Handle the heavy ball carefully to avoid damaging the setup.

CONCLUSION

This project helped demonstrate how massive objects curve space-time and influence the motion of objects and light. The stretched fabric model showed how a massive object can bend the surrounding space-time. This model made it easier to understand Einstein's General Theory of Relativity. The study also highlighted important applications of space time curvature, including GPS technology, black hole imaging, astronomy, and space exploration. Overall, the project shows that space time curvature is a fundamental concept with significant scientific and real-world importance.
